## Performance Measures for Regression Tasks

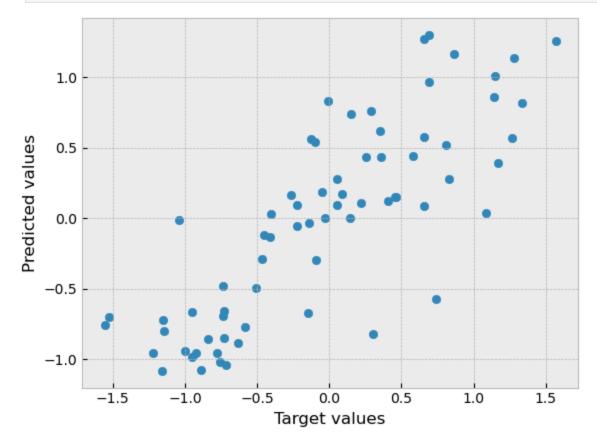

In order to determine if the model is able to **generalize** to a **validation set**, we need to determine a **performance measure**.

Which measures would you use to compare model performances?

- 1. Error measures are always a good start for **regression** tasks. Some examples include:
  - Mean Squared Error (MSE) best when the data does not have outliers. The MSE will penalize outliers heavily.
  - Mean Absolute Error (MAE) best when you suspect data has outliers.
  - Normalized mean squared error (NMSE).

- Normalized mean absolute error (NMAE).
- 2. Coefficient of Determination  $r^2$ 
  - ullet Advantage: it is bounded between [0,1], where values closer to 1 indicate a better prediction.
- 3. Quantile-Quantile plot (or Q-Q plot)
  - Qualitative measurement of the model predictions vs the target values.
  - The Q-Q plot is used to answer the following questions:
    - Do two data sets come from populations with a common distribution?
    - Do two data sets have common location and scale?
    - Do two data sets have similar distributional shapes?
    - Do two data sets have similar tail behavior?

```
In [6]: plt.scatter(t_train, y)
   plt.xlabel('Target values')
   plt.ylabel('Predicted values');
```

```
In [7]: ## Predictions in training/test sets with and without regularization
y = PolynomialRegression_test(x_train, w)
y_test = PolynomialRegression_test(x_test, w)

y_reg = PolynomialRegression_test(x_train, w_reg)
y_test_reg = PolynomialRegression_test(x_test, w_reg)

## Error Measures
```

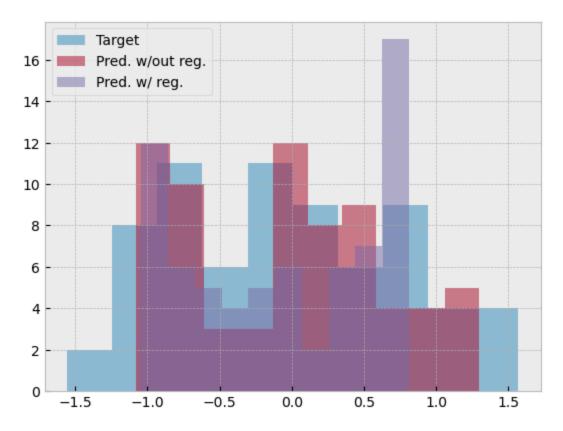

```
error train = t train - y
        error train reg = t train - y reg
        # Residual error for Test data for polynomial regression without and with re
        error_test = t_test - y_test
        error_test_reg = t_test - y_test_reg
        # Error Measures
        print('Mean Squared Error \n')
        print('Training Set')
        print('Without regularizer: ', np.mean(error_train**2))
        print('With regularizer: ', np.mean(error_train_reg**2),'\n')
        print('Test Set')
        print('Without regularizer: ', np.mean(error_test**2))
        print('With regularizer: ', np.mean(error_test_reg**2),'\n')
        print('-----
        print('Mean Absolute Error \n')
        print('Training Set')
        print('Without regularizer: ', np.mean(np.abs(error_train)))
        print('With regularizer: ', np.mean(np.abs(error_train_reg)),'\n')
        print('Test Set')
        print('Without regularizer: ', np.mean(np.abs(error_test)))
        print('With regularizer: ', np.mean(np.abs(error_test_reg)),'\n')
       Mean Squared Error
       Training Set
       Without regularizer: 0.20444327661371497
       With regularizer: 0.15203267196569925
       Test Set
       Without regularizer: 0.37670836082928333

In practice, we consider a good fit if the r^2 of the Q-Q plot if greater than 0.9, ideally >0.99.
```

## **Other Performance Measures**

Performance of an algorithm can be determined using a variety of statistical goodness-of-fit measures.

- For regression tasks this includes error-based measurements, hypothesis tests, Q-Q plots.
- For classification tasks this includes error rate, accuracy, ROC curves, performancerecall curves.

But it can also be in terms of:

- 1. Risk,
- 2. Training time,
- 3. Training storage/memory,
- 4. Testing time,
- 5. Testing storage/memory,
- 6. Interpretability, namely, whether the method allows knowledge extraction which can be checked and validated by experts, and
- 7. computational complexity.

# Strategies to Mitigate Overfitting

- 1. Add more data! when possible
- 2. Occam's Razor select a model with lower complexity
- 3. Regularization constrains/regularizes the coefficients of the model
- 4. Cross-validation technique for utilizing the training data to fine-tune hyperparameter values

## **Cross-Validation**

The goal of **cross-validation**, or CV, is to test the model's ability to predict new data that was not used in estimating the model, in order to flag problems like overfitting or selection bias and to give an insight on how the model will generalize to an independent dataset (i.e., an unknown dataset).

Cross-validation allows us to determine the values for the hyperparameter that provide the most **generalization**. Cross-validation mitigates the occurrence of overfitting, but it does not eliminate it entirely.

#### Suggested reading:

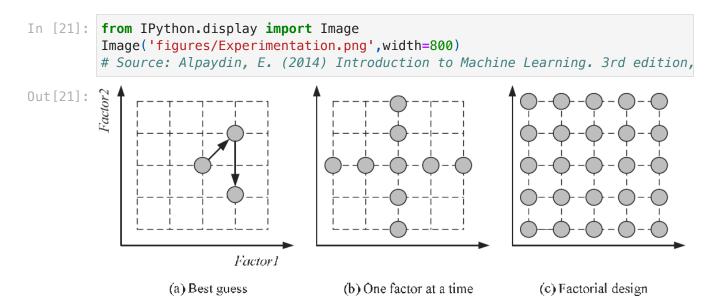

- Sections 19.1-19.6 from the Alpaydin textbook
- Section 5.3 Hyperparameters and Model Validation from the "Python Data Science Handbook" textbook.

# Strategies of Experimentation - Fine-Tuning Hyperparameters

To fully test a system, you want to try to evaluate each of these parameters separately. However, this is often not easily done.

A few strategies for fine-tuning hyperparameters include:

- Best guess
- One factor at a time
- Factorial design or grid search
- Randomized search

We first must select a **performance measure**, e.g. mean square error (MSE), coefficient of determination  $r^2$ . There are different strategies for implementing cross-validation:

- 1.  $k \times 2$  cross-validation
- 2. k-fold cross-validation
- 3. Leave-One-Out cross-validation
- 4. Stratified cross-validation

We also need to make sure that classes are represented in the right proportions when subsets of data are held out, not to disturb the class prior probabilities; this is called **stratification**. If a class has 20 percent examples in the whole dataset, in all samples drawn from the dataset, it should also have approximately 20 percent examples.

## $1 \times 2$ cross-validation

Let's consider the case, where we only have a single validation set which resulted from splitting the training data into a training set and a validation set with splitting rations 70% and 30% respectively.

```
In [22]: from sklearn.model_selection import train_test_split

x_train2, x_validation, t_train2, t_validation = train_test_split(x_train, t test_size= shuffle=Tr random_stat

x_train2.shape, x_validation.shape, t_train2.shape, t_validation.shape
```

```
Out[22]: ((49,), (21,), (49,), (21,))
```

Let's now vary the values for M and estimate the associated coefficients  ${\bf w}$  using the training set. Then, let's evaluate performance measure (e.g. MSE) in both training and validation sets:

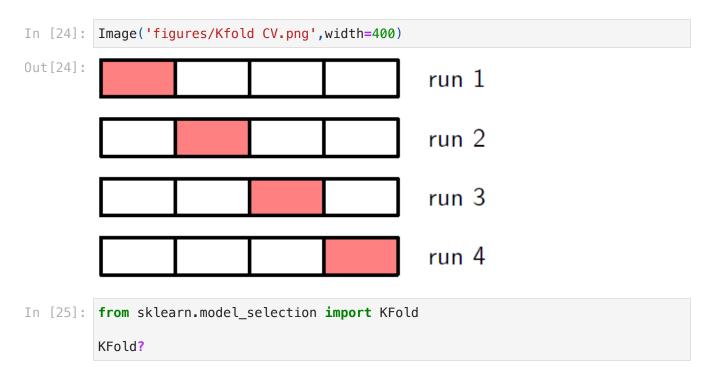

```
In [23]: # Range of values for M
         M_{vals} = range(1,11)
         perf train = []
         perf val = []
         for M in M_vals:
             # Train the model (without regularization for simplicity of illustration
             w, y_train = PolynomialRegression(x_train2, t_train2, M)
             # Make predictions for the training and validation sets
             y_validation = PolynomialRegression_test(x_validation, w)
             # Performance Measure (MSE)
             perf_train += [np.mean(t_train2-y_train)**2]
             perf_val += [np.mean(t_validation-y_validation)**2]
         # Plotting results
         plt.figure(figsize=(10,3))
         plt.plot(M_vals, perf_train, '-og', label='Training Set')
         plt.plot(M_vals, perf_val, '-or', label='Validation Set')
         plt.legend(fontsize=15)
         plt.xlabel('Model order, $M$', size=12)
         plt.ylabel('Performance Measure', size=12);
```

### K-Fold Cross-Validation

The technique of k-fold cross-validation, illustrated below for the case of k=4, involves taking the available data and partitioning it into k groups (in the simplest case these are of equal size). Then k-1 of the groups are used to train a set of models that are then evaluated on the remaining group. This procedure is then repeated for all k possible choices for the held-out group, indicated in the picture below by the red blocks, and the performance scores from the runs are then averaged.

K is typically 10 or 30. As K increases, the percentage of training instances increases and we get more robust estimators, but the validation set becomes smaller. Furthermore, there is the cost of training the classifier K times, which increases as K is increased. As N increases, K can be smaller; if N is small, K should be large to allow large enough training sets.

**Goal:** find the best value for the **hyperparameters** M (model order) and  $\lambda$  (regularization trade-off parameter).

#### Let's use **4-fold cross-validation** on this data:

```
In [39]: k = 4 # number of folds

kf = KFold(n_splits=k,shuffle=True, random_state=0)
kf

Out[39]: KFold(n_splits=4, random_state=None, shuffle=True)

In [40]: # Split training feature matrix into training and validation sets

f=1
    for train_index, validation_index in kf.split(x_train):
        print('Fold ', f)
        print('The training set has ', train_index.shape[0],' samples')
        print('Their index locations are: ', train_index.shape[0],' samples')
        print('Their index locations are: ', validation_index.shape[0],' samples')
        print('Their index locations are: ', validation_index,'\n')
        f+=1

# [ 9 15 17 18 24 27 29 34 36 37 40 44 45 49 54 64 65 68]

### Discussion

- We select the set of hyperparameters  $\{M,\lambda\}$  with the best performance score (e.g. smallest MSE or largest  $r^2$ ).
- If the value of the hyperparameter falls at the edge of provided range of values, it is appropriate to expand the range of values for further exploration.
- Other performance measures can be used, for example, the coefficient of determination of the Q-Q plot for regression tasks, or accuracy score for classification tasks.

## Leave-One-Out Cross-Validation

One extreme case of cross-validation is the **leave-one-out** where given a dataset of N instances, only one instance is left out as the validation set (instance) and training uses the N-1 instances. We then get N separate pairs by leaving out a different instance at each iteration. This is typically used in applications such as medical diagnosis, where labeled data is hard to find. Leave-one-out **does not permit stratification**.

#### The No Free Lunch Theorem

The No Free Lunch Theorem states that there is no single learning algorithm that in any domain always induces the most accurate learner. The usual approach is to try many and choose the one that performs the best on a separate validation set.

For any learning algorithm, there is a dataset where it is very accurate and another dataset where it is very poor. When we say that a learning algorithm is good, we only quantify how well its inductive bias matches the properties of the data.

# The Curse of Dimensionality

The Curse of Dimensionality illustrates various phenomena that arise when we work with high-dimensional data spaces that would not otherwise occur in lower-dimensional settings (such as the 3-dimensional space).

Our intuitions do not hold in high-dimensional spaces (9)

Let's illustrate this with two examples.

# **Example 1: Volume of a Crust**

Consider two embedded spheres,  $S_1$  and  $S_2$ , where sphere  $S_1$  has radius r, sphere  $S_2$  has radius  $r-\epsilon$ , with  $0<\epsilon< r$ .

Let's calculate the ratio between the volume of the crust and the volume of the outer sphere  $S_1$ :

$$ext{ratio} = rac{V_{crust}}{V_{S_1}} = rac{V_{S_1} - V_{S_2}}{V_{S_1}}$$

ullet The D-dimensional volume of a sphere of radius r in D-dimensional space is:

$$V=rac{r^D\pi^{rac{D}{2}}}{\Gamma\left(rac{D}{2}+1
ight)}$$
 , then

$$egin{aligned} ext{ratio} &= rac{V_{S_1} - V_{S_2}}{V_{S_1}} \ &= 1 - rac{V_{S_2}}{V_{S_1}} \ &= 1 - rac{rac{(r - \epsilon)^D \pi^{rac{D}{2}}}{\Gamma\left(rac{D}{2} + 1
ight)}}{rac{r^D \pi^{rac{D}{2}}}{\Gamma\left(rac{D}{2} + 1
ight)}} \ &= 1 - rac{(r - \epsilon)^D}{r^D} \ &= 1 - rac{r^D \left(1 - rac{\epsilon}{r}
ight)^D}{r^D} \ &= 1 - \left(1 - rac{\epsilon}{r}
ight)^D \end{aligned}$$

• For a fixed value for  $\epsilon$ , a fixed radius r and  $\epsilon < r$ , what happens as D increases?

```
In []: # Crust volume between spheres with epsilon different radii and increasing of
r = 1 # radius of outer sphere
eps = 0.001 # epsilon value
D = range(1,10000) # dimensionality
RatioVol = [1-(1-eps/r)**d for d in D] # ratio of the volume as a function of
plt.plot(D, RatioVol) # plotting results
plt.ylabel('ratio$=1 - (1 - \epsilon/r)^D$',size=15)
plt.xlabel('(Feature Space) Dimensionality, D',size=15);
```

## Let's see another example!

## **Example 2: Unit Porcupine**

Consider the unit porcupine which is represented as a unit hypersphere inscribed within a unit hypercube.

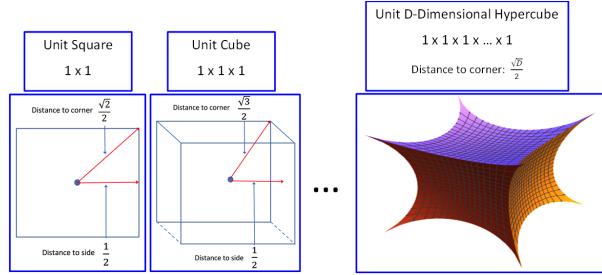

Recall that the D-dimensional volume of a D-dimensional cube with radius r is  $(2r)^D$ .

ullet What happens to the ratio between the volume of the sphere and the volume of the cube as dimensionality D increases?

$$egin{split} rac{V( ext{sphere})}{V( ext{cube})} &= rac{rac{r^D\pi^{rac{D}{2}}}{\Gamma\left(rac{D}{2}+1
ight)}}{(2r)^D} \ &= rac{r^D\pi^{rac{D}{2}}}{(2r)^D\Gamma\left(rac{D}{2}+1
ight)} \ &= rac{\pi^{rac{D}{2}}}{2^D\Gamma\left(rac{D}{2}+1
ight)} \end{split}$$

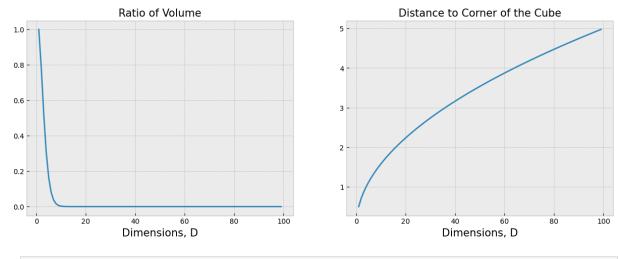

```
In [42]: # The Unit Porcupine (the unit hyper-sphere inscribed within the unit hyper-
import math

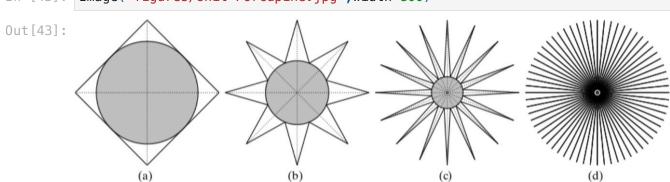

D = range(1,100) # dimensionality, D
V = [np.pi**(i/2)/(2**i*math.gamma(i/2 + 1)) for i in D] # ratio as a functidist_to_Corner = [math.sqrt(d)/2 for d in D] # distance

# plotting
plt.figure(figsize=(15,5))
plt.subplot(1,2,1); plt.plot(D, V)
plt.title('Ratio of Volume',size=15)
plt.xlabel('Dimensions, D',size=15)

plt.subplot(1,2,2)
plt.plot(D, dist_to_Corner)
plt.title('Distance to Corner of the Cube',size=15)
plt.xlabel('Dimensions, D',size=15);
```

In [43]: Image('figures/Unit Porcupine.jpg',width=800)

## **Discussions**

In the unit porcupine example, for higher-dimensionality D, all of the volume will reside in the "corners". So, distances between neighboring points is extremely large. The notion of **similarity** as measure by distances becomes a challenge.

As the dimensionality of the feature space increases, we need exponentially more data in order to explain a highly increasing volume.

We need to be careful choosing a model as that choice "injects" what we want the data to look like or follow a specific behavior. For example, in higher-dimensions, the tails of a Gaussian density function will become highly dense.

Always employ the **Occam's Razor** principle: the simplest model that works for our data is usually the most appropriate and sufficient. Model simplicity can mean different things, but we can consider a model to be complex if it has too many hyperparameter values to configure.

When we are in a high-dimensional input space (such as images), much of that space is empty. The input data can be represented in only a few *degrees of freedom* of variability. We say that the data in *embedded* in a **manifold** of equal dimensionality as the degrees of freedom (which is drastically smaller than the input space dimensionality). We will

study a few dimensionality reduction and manifold learning techniques later on in this
course.
And again, intuitions or assumptions do not always hold in higher dimensions.
